#### Abstract

Based on the fractal theory, the spatial structure of China's vegetation has been analyzed quantitatively in this paper. Some conclusions are drawn as the following. 1) The relationships between size and frequency of patch area and patch shape index exist objectively for China's vegetation. 2) The relationships between perimeter and area exist objectively for China's vegetation. 3) The fractal dimension of evergreen needleleaf forests on mountains in subtropical and tropical zones is the largest, while the smallest for deciduous broadleaf and evergreen needleleaf mixed forests in temperate zone, reflecting the most complex spatial structure for evergreen needlleleaf forests on mountains in subtropical and tropical zones and the simplest for deciduous broadleaf and evergreen needleleaf mixed forests in temperate zone. 4) The fractal dimensions of China's vegetation types tend to decrease from the subtropics to both sides. 5) The stability of spatial structure of deciduous broadleaf and evergreen needleleaf mixed forests in temperate zone is the largest, while the smal lest for double cropping rice, or double cropping rice and temperate like grain, and tropical evergreen economic tree plantations and orchards, reflecting the steadiest for deciduous broadleaf and evergreen needleleaf mixed forests in temperate zone and the most unstable for double cropping rice, or double cropping rice and temperate like grain, and tropical evergreen economic tree plantations and orchards in spatial structure. 6) The stability of spa tial structure of China's vegetation tends to decrease from the temperate zone to both sides. It is significantly pertinent to understand the formation, evolution, dynamics and complexity rule of ecosystem of vegetation. ## 1INTRODUCTION

Mandelbrot stated the uncertainty of the length of a coastline in his paper "How long is the coast of Britain? Statistical self-similarity and fractional dimension" published in Science in 1967 (MA NDELBROT, 1967). The concepts of fractal and fractal dimension were presented for the first time in that paper and have been applied to quantitatively describing the difference of crooked coastlines of British and South A frica. Compared with the Euclidean geometry with more than two thousand years of history, fractal and fractal dimension are fitter for describing various compli cated objects in nature.

The fractal theory has been applied in many fields. At present it has become a field with vast potential for its applications in many disciplines. It has been applied extensively in botany too. For instance, MORSE et al.,
(1985) studied the relationship between fractal dimension of vegetation and distribution of anthropod body lengths. ZEIDE and PFEIFER (1991) designed a method for estimation of fractal dimension of tree crowns. LOEHLE et al., (1996) applied the fractal theory to indicating the forest spread and phase transitions at for-est-prairie ecotones in Kansas, USA. XIN et al., (1999) analyzed the fractal characteristic of grass patches under grazing and flood disturbance in alkaline grassland of the Songnen Plain, China. MA and ZU (2000) studied the fractal properties of vegetation pattern. LIU and CAMERON (2001) analyzed the landscape fractal patterns in coastal wetlands of Galveston Bay, Texas, USA . PERRY et al. ( 2001) described a spatially explicit, land-scape-level model developed to investigate the vegeta tion pattern on Mont Do, New Caledonia. DESPLAND (2003) evaluated box-counting dimension as a quantita

[^0]tive clumping index for discontinuous plant cover, and applied it to studies of both small- and large scale ecological processes in desert locust swarming. ALA DOS et al. (2003) studied the effect of grazing on the degree of regression of successional vegetation dynamics in a se-mi-arid Mediterranean matorral, and quantified the spa tial distribution patterns of the vegetation by fractal analyses. A lthough related studies have been done, the references on spatial fractal structure of vegetation on larger scale have not been seen until now. Different types of vegetation display patches with different magnitude and distribution of oddsin space that impliesthat there might occur significant variability in the spatial distribution of different types of vegetation. Based on the fractal theory, it is significant to study the character of spatial distribution of different types of vegetation to systematically understand the formation, evolvement and commonness rule of ecosystem of vegetation.
V egetation types of China are abundant, most typesbe ing distributed in China. Therefore, China with an area of $9.6 \times 10^{\circ} \mathrm{km}^{2}$ is a region suitabl e for studying the spatial fractal structure of vegetation. This paper focused on four problems. Firstly, the relationship between size and frequency of patches of vegetation types of China; se condly, the relationship between perimeter and area of patches of vegetation types of China; thirdly, the fractal dimensions of spatial structure of vegetation types in China; and fourthly, the stability of spatial structure of vegetation types of China.

## 2METHODSANDMATERIALS

According to the fractal theory, the relationships between size and frequency of patches of vegetation types of China were established. The basic fractal formula of size frequency is asfollows(TURCOTTE, 1986):

$$
\begin{equation*}
N(>r)=\frac{c}{r^{d}} \tag{1}
\end{equation*}
$$

where $r$ is size, $N(>r)$ is frequency above size $r, c$ is a constant, d isfractal dimension.

In this paper, $r$ in formula (1) is defined as patch area and patch shape index respectively. N in formula (1) is defined as the number of vegetation patches above sizer.
Formula of patch shape index contrasted with square is expressed as(WU, 2002):

$$
\begin{equation*}
S=\frac{0.25 \times P}{\sqrt{A}} \tag{2}
\end{equation*}
$$

where $S$ is patch shape index, P is patch perimeter and A is patch area.

The relationship between perimeter and area of patchesis established by fractal formula (3) (LOREJOY,

1982; MA NDELBROT et al., 1984).

$$
\begin{equation*}
A=k P^{2 D} \tag{3}
\end{equation*}
$$

where $A$ is patch area, $P$ is patch perimeter, $D$ is fractal dimension, k is a constant. Formula (3) may be trans formed by logP against logA, then

$$
\begin{equation*}
\log A=\frac{2}{D} \log P+C \tag{4}
\end{equation*}
$$

Fractal dimension of spatial structure of vegetation can be cal culated by formula (4). The slope of the regression line of series of logP against logA is 2/D. Larger the value of $D$, more complex isthe spatial structure. When $D$ is equal to 1.5 , spatial structure is most unstable, because it is in a random condition of Brownian movement (XU, 2002). When D is closer to 1.5 , spatial structure is unsta ble. The stability index of spatial structure of vegetation is established as (X U, 2002):

$$
\begin{equation*}
\mathrm{SK}=1.5 \mathrm{D} \tag{5}
\end{equation*}
$$

Larger the value of SK, steadier is the spatial structure of soil.
The data used are from "Resources and Environment Database of China (1: 4000 000)" prepared by the State Key Laboratory of Resources \& Environment Informa tion System of Chinese A cademy of Sciences in 1996. V egetation data of the database are from "China's V egetation Map (1: 4000 000)" (Institute of Botany, Chinese A cademy of Sciences, 1979). China's V egetation Map in this database was vectorized through Arc/nfo, popular GIS software, and data capacity reached 16936965 bytes. In this database, information of perimeters and areas of patches of different types of vegetation can be read and then calculated on the basis of formulas(1) - (5) through Excel software. Based on formulas (1) and (4), linear regressions of double logarithms were done, and then significance tests were done using the critical value of correlation coefficient (YUAN and ZHOU, 2003). The vegetation types in this database are classified as natural vegetation, cultivated vegetation, land without vegetation, and lake.

Natural vegetation is classified as 43 types, whose names and codes are as follows: deciduous needleleaf forests on mountains in cold-temperate and temperate zones (1101), evergreen needleleaf forests on mountains in temperate zone (1102), evergreen needleleaf woodland on sandy land in steppe in temperate zone (1103), evergreen needleleaf forests in temperate zone (1104), evergreen needleleaf forests in subtropical and tropical zones (1105), evergreen needleleaf forests on mountains in subtropical and tropical zones (1106), deciduous broadl eaf and evergreen needleleaf mixed forests in temperate zone(1207), deciduous broadleaf forests in temperate and subtropical zones (1208), microphyllous de
ciduous forests on mountains in temperate and subtropical zones(1209), microphyllous deciduous woodland in temperate zone (1210), broadleaf deciduous and evergreen mixed forests on calcareous soil in subtropical zone (1211), broadleaf evergreen and deciduous mixed forests on mountainous acid yellow soil in subtropical zone (1212), evergreen broadleaf forests in subtropical zone (1213), evergreen broadleaf forests with characters of tropical rain forests (1214), sclerophyllus evergreen broadleaf forests in subtropical zone (1215), bamboo forests in subtropical zone (1216), semi-evergreen broadleaf monsoon forests and second birth vegetation in tropical zone (1217), evergreen broadleaf rain forests and second birth vegetation in tropical zone (1218), deciduous scrubs and dwarf forests in temperate and subtropical zones (1319), broadleaf evergreen and deciduous scrubs and dwarf forests and tufted-grass on acid soil in subtropical and tropical zones (1320), evergreen and deciduous scrubs and dwarf forests with many sorts of lianes (1321), sclerophyllus broadleaf evergreen scrub and dwarf forests on seaside areas in tropical zone (1322), broadleaf evergreen succulent scrub and dwarf forests on coral islands in tropical zone (1323), al pine and subal pine sclerophylla evergreen scrubes in subtropical zone (1324), subal pine deciduous scrubs in temperate and subtropical zones (1325), al pine tundra with dwarf scrubes in temperate zone (1326), al pine cushion dwarf semi-shrub in temperate and subtropical zones (1327), dwarf semi-shrub deserts in temperate zone
(1428), succulent hal ophytic dwarf semi- shrub deserts in temperate zone (1429), shrub and semi- shrub deserts in temperate zone (1430), semi-arboreous deserts in temperate zone (1431), high-cold cushion dwarf semi-shrub deserts in temperate zone (1432), temperate grass, forb steppes (1533), temperate tufted grass steppes (1534), temperate tufted grass steppes on mountains (1535), temperate tufted low grass, dwarf semi-shrub steppes (1536), temperate Iow grass, dwarf semi-shrub steppes on mountains(1537), high-cold steppes in temperate and subtropical zones (1538), sparse shrub steppes in tropical and subtropical zones (1539), temperate meadows (1640), high-cold meadows in temperate and subtropical zones (1641), temperate herbage marsh (1642), temperate high-cold herbage marsh(1643).

Cultivated vegetation is classified as 5 types, whose names and codes are as follows: one year one ripe grain and cold-tolerant economic crop (2100), one year two ripes or two year three ripes grain (rice locally) and deciduous orchards, economic tree platations in warm-temperate zone (2200), one year two ripes (grain and rice) and subtropical evergreen, deciduous economic tree plantations and orchards(2300), Single(double)cropping rice and cool-like grain, or one year three ripes (2400), double-cropping rice, or double-cropping rice and temperate-like grain, and tropical evergreen economic tree plantations and orchards(2500).

The vegetation types and patch number of China are listed in Table1.

## 3RESULTS

3.1Relationship of Size-fr equency of Patch A rea Sizer in formula(1) is defined as patch areahere. Theresult of size-frequency of patch areas of the whole China's vegetation types are listed in T able 2, and those of different vegetation types of China are listed in Table 3. Some ef vegetation types are not listed in Table 3 because the
patch number is not enough.
Table 2 showsthat the patch number of the whole China's vegetation types is 5466 pieces above size $50 \mathrm{~km}^{2}$, and it is 27 pieces above size $50000 \mathrm{~km}^{2}$.

Plot of $\log N(>r)$ against logr of patch areas of the whole China's vegetation ty pes is shown in Fig. 1.

A ccording to the least square method, the relationship ibetween sizel and frequency of patch areas pf che whole

Fig. 1Plot of $\log N(>r)$ against logr of patch area of wholeChina'svegetation type

China's vegetation types is established by linear regre ssion asfollows:

$$
\begin{equation*}
\log N=5.4383-0.832 \operatorname{logr} \tag{6}
\end{equation*}
$$

Similarly, the relationship of size-frequency of each vegetation type may be established. The results are listed in Table 4.

The relationships of size frequency of all vegetation types can pass the $R$ test ( $\mathrm{R}_{0.06} \geq 0.8783$ ), which ascer-
tains the significance of relationships of size frequency of China's vegetation types.
3.2Relationship of Size frequency of Patch Shape Index
Size $r$ in formula (1) is defined as patch shape index here. Size frequency relationship has been computed us ing formula (1). The results are listed in Table 5 and Table6.

Plot of $\log N(>r)$ against logr of patch shape index of the wholeChina'svegetation types is shown in Fig. 2.

The relationship between size and frequency of the whole China's vegetation types is established through linear regression as:

$$
\begin{equation*}
\log N=3.6912-2.60291 \mathrm{ogr} \tag{7}
\end{equation*}
$$

Relationship of size frequency of each vegetation type can be established by the same method. The results are listed in Table 7 .

The relationships of size frequency of patch shape index of China's vegetation types can pass the R test-

Fig. 3 Plot of logP against logA of patches of whole China's vegetation types
types of China(D) have been calculated by incorpora ting the area and perimeter values from T able 8 into thee quation (4) and the results obtained are presented in Table9.
Table 9 shows that the fractal dimension of evergreen needleleaf forests on mountains in subtropical and tropical zones(1106) isthe largest, while smal lest for deciduous broadleaf and evergreen needleleaf mixed forests in temperate zone (1207), implying that the spatial structure of 1106 isthe most complex while that of 1207 is the simplest. Based on this inference, fractal dimension could be considered as a vital parameter to describe the spatial structure of China's vegetation. The complexity

wardsitsboth sides.
3.5 Stability Index of Spatial Structure of China's V egetation Type
Using the fractal values from Table 9 in equation (5), sta bility indexes SK of spatial structure of vegetation types of China are calculated and listed in T able 11.

Table 11 shows that the stability of spatial structure of 1207 (deciduous broadleaf and evergreen needleleaf mixed forests in temperate zone) is the largest, while smallest for 2500 (double-cropping rice, or double-cropping rice and temperate-like grain, and tropical evergreen economic tree plantations and orchards). The sta bility structure of China's vegetation types is arranged as follows:
$1207>1102>1104>1326>1643>1106>1325>2300>$
$1103>1208>1324>1432>1536>1209>1533>1101>$
$1215>1534>1214>2400>1429>1320>1430>1218>$
$1535>1537>1216>1640>1319>1641>1642>1211>$
$1212>2100>1210>1105>1431>1327>1428>2200>$
$1217>1538>1321>1213>1539>2500$.
Table 12 lists the average stability indexes of vegeta tion types in different climatic zones in China.
temperate zone's vegetation types is the largest, reflecting the steadiest spatial structure for temperate zone's vegetation types, and it tends to decrease towards both sides.

## 4 CONCLUSIONS

Quantitative analyses of the spatial distribution of vegetation types of China were performed. Not only the quantitative relationship between the perimeter and area of patches of various types of vegetation was es tablished, but also the fractal dimension and stability indexes of different types of vegetation were further es timated. They are the characteristic parameters for quantitatively describing the ecosystem of vegetation types of China. V egetation system is an outcome of long-term evolution and combined action of nature and human factors. This process led to the formation of complex natural cum human-induced fractal objects within the vegetation pattern that can be characterized by thorough understanding of the fractal dimension and its variability in relation to the climatic conditions and seasonal variations. It is significantly pertinent to under-
